

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

Background and Context

Soccer has long and widely been regarded as the most popular sport in the world. Although it does not have the same monetary incentives as certain other sports such as American football and basketball, soccer has seen fast rising income. This is primarily due to increase in prize moneys from participating and winning in tournaments, more money from more types and bigger sized sponsorship deals for clubs, and constant rise in earnings from ticket sales; simultaneously, there has been improved cost control with better management of player and staff wages and efficient methods of stadium maintenance. We know that the world of finance is such that investors will attempt to exploit all avenues that seem lucrative, whether they are technology startups, healthcare, finance or even sports. It is not surprising then that soccer is witnessing an increase in investments by individuals and financial institutions. For most clubs an increase in investment primarily results in an increase in the transfer budget to purchase players in the transfer market from other teams. Just like any economic market, the soccer transfer market is such that as more money is pumped into this system, while keeping supply of players constant, the price of each player will increase.

In this paper I attempt to develop a statistical model that can predict transfer values of soccer players based on easily observable player attribute data obtained from the EA Sports FIFA (hereon referred to as FIFA) video games and no other external factors besides the ones accounted for by FIFA in determining the attribute ratings. The next section highlights the importance of this research with regard to the timing of the paper and ever-increasing transfer budgets being allocated to managers. The section after that will delve into existing research in this domain and the need for a different focus in determining transfer value based on internal skill ratings to objectify a true market value. Finally, the paper will describe the data mining and analysis processes to develop a model that is fairly comprehensive, but with its fair share of limitations that have been outlined for further research.

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

Purpose

The purpose of this research is to develop a statistical model that can player's skill ratings from a video game to predict true market value of soccer attributes in real life. This research paper will attempt to provide analytical insight into the functioning of a market that has thus far witnessed very limited, if any, analytical scrutiny. I believe that a soccer player is to soccer what a production line is to a manufacturing company – they are crucial assets whose 'price' can be determined based on several factors related to the asset's (player's) attributes. This research will attempt to predict transfer value based on isolated individual players' attributes data independent of the team that they play for by using individual attribute data as compared to performance metrics of the player.

The paper will also capture the attributes on FIFA that are more significant in determining players' transfer values, and how these attributes correlate to the transfer values of the respective players in real life. The results will also be used to assess whether the key attributes identified on FIFA for a particular position are the same as the commonly acknowledged key attributes of the respective position in real life. People often question the accuracy and judgment of scouts in successfully identifying top players from a group of five year olds. Is there some innate holistic game sense in five year olds than scouts are successful in spotting or do scouts simply select players that are fast or hit hard or tackle well? I want to address this question by looking at whether players gain their transfer values based on the two key attributes for that position or whether the holistic composition of all their attributes along with form determines the transfer value.

Through this research, I also want to see whether individuals involved in the transfer making process are overvaluing certain unobserved qualities such as age or potential. This question arises due to the ever-increasing transfer budgets allocated to managers to successfully complete transfers, resulting in the ancestral economic problem of too much money chasing too few goods.

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

Motivation

This is a worthwhile question because I am attempting to provide an objective understanding of how a player's attributes determine his transfer value in the soccer transfer market, independent of other factors surrounding the sport. This moves away from typical analyses of how performance statistics such as goals scored, assists, clean sheets, etc. correlate to the transfer value as I believe they cloud the true measure of the individual's capabilities. I strongly believe that a player's attributes are independent of the team they play for, whereas the same player's performance statistics, such as those aforementioned, are highly dependent on the other players in their team. There is no clear way of determining whether the model's results are justified, as there is no 'true' market value assigned to a player. However, I will compare my model's predictions to the actual transfer value data as well as to the 'true' market value predictions made by experts in the field of soccer data analytics. My model is also highly likely to generate negative transfer values for some players, which is simply a factor of the strong negative relationship between age and transfer values, along with low attribute ratings. The model does not fully account for three important factors,

- i. external factors and off-the-pitch attitude such as experience, status, etc. because some managers value experience more than others and hence are willing to pay more for more experienced players, while club directors looking to make lucrative deals desire players that can increase fan base, merchandise sales, ticketing sales, etc.
- ii. 'emergency transfers' being made in the winter transfer window, where managers are willing to pay more for a player because they are in dire need of any player to fulfill that position.

I am also strongly inclined towards the fact that scouts seek more than just two attributes in distinguishing between good and bad players. Therefore, I want to compare the explanation provided by overall ratings of players to the transfer value, with the explanation provided by the two key attributes to the transfer value. I expect,

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

quite intuitively, that overall ratings will fit the transfer value data better suggesting that a player who is the best at the two key attributes may still be undervalued to a player who is not as good in the two key attributes but better overall. If the results suggest that the two key attributes correlate more closely to the transfer value data then one can successfully question the utility of scouts in this process.

This paper also comes at a good time with last year's winners, Leicester City, proving to be a strong contradiction to the rising popular belief that "money wins matches" as clubs backed by strong funding were consistently winning the English Premier League. I believe that the influx of capital is leading to a formation of a bubble in the transfer market with attributes such as age and factors such as status being overvalued and the average age of players being transferred decreasing, insofar as the aforementioned external factors not accounted for in this paper are also becoming more statistically significant in determining the transfer value. If this is true, then this enables directors to use the transfer market solely as a profit generating mechanism with acute purchase and sales of players from and to other teams.

Literature

There is very limited prior research in this area, but existing research topics fail to address the question I am raising in my paper. Existing literatures attempt to identify the parameters that most significantly contribute to the transfer value, but do not focus on individual player attributes as a parameter. A potential reason for all articles intentionally avoiding using FIFA attribute data is that they strongly believe that these rankings are arbitrary – they are not objective facts like the number of goals scores or games played, and are likely to be prone to subjective biases. Hence, they consider several parameters including non-player related factors, such as league, contract status, international team status, size of buying club, as well as several player performance factors such as goals scored, image rights, iconic status, age, position, etc. to predict transfer values based on transfer values thus far. Commonalities between the different

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

existing literatures indicate that the significant parameters in determining transfer value are

- i. games played, where the transfer value is increasing in number of games played
- ii. goals scored, where the transfer value is increasing in number of goals scored
- iii. age, where the transfer value is increasing in age until the peak year of 28, after which the transfer value starts decreasing
- iv. size of buying club, where the transfer value is increasing in size of buying of club
- v. club quality, where the transfer value is increasing in quality of club

A major limitation of these models is the inherent collinearity between predictor variables in the model. On average, players with more games have score more goals, simply because they had more opportunities to do so given that they played more minutes. Similarly, games played and age is highly correlated for players between the ages of 25 and 28, considered peak years in the soccer world. This is when the player is at his prime, in terms of skill and fitness, and managers seek to maximize the utility of the player, thereby giving the player more games to play. Much like in any other sport, this relationship is parabolic with game time increasing in age up until the peak age, before decreasing again. Size of buying club and club quality are also highly correlated because bigger clubs attract better managers and players, while simultaneously, the size of buying club increases with improvement in club quality, because the club gets access to a bigger monetary prize pool.

The most comprehensive model is one developed by CIES Football Observatory that provides an online transfer value calculator taking into account the aforementioned parameters and more to predict a trajectory of the player that provides a transfer value. However, there are the following important weaknesses in the model developed by CIES. The public is allowed to markup and markdown the predicted transfer values,

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

introducing personal biases in the transfer values. The predicted transfer values that are reported are influenced by the number of markups and markdowns and have an upwards bias with the public marking-up their favorite players' transfer values. Moreover, CIES do not publicize the econometric models they have developed, where they might be assigning higher weights to performance statistics parameters. The scenarios delineated below can cause several problems to the model if the performance statistics parameter is weighted high:

- i. players transferring to a manager with a different mindset – if an attacking player plays for a defense-minded manager, the player is likely to get fewer goals which will negatively affect his transfer value. This is very problematic as the player is likely to have the same attacking instinct and improve on his defensive qualities, but still face a fall in transfer value
- ii. players transferring to a better team that is stricken with injuries – if a goalkeeper transfers to a better team that has its best defenders injured, then the goalkeeper is likely to concede more goals due to no fault of his own
- iii. players transferring to different climates, regions, and physical conditions resulting in injuries – the English Premier League is considered to be a bigger physical test than some other leagues due to the high physicality of players, volatile climate, and belligerent fans. If a player transfers

These are some reasons why the weights assigned to performance metrics might be too high in determining transfer value and hence, might result in a decrease in transfer value even though the player's talent is growing. This issue is common to all research that correlates objective statistics for individuals in team games. There is no constant effect of the team on an individual player, as the team is made up of 24 other such individual players where each one relies on the other. According to these models then, it is statistically unjustified to compare players from two different teams, leagues, or

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

countries, as they do not share the same externalities. A justified comparison in these models can then only be between players playing at the same time within the same team. Hence, it is naïve to not consider the entire system the individual player is in if using external factors as parameters, and simultaneously impossible to account for the entire system as a constant or fixed effect.

My research will mitigate the following weakness by removing the player from the system he is in and analyzing his value primarily as a function of his attributes. The attribute rankings are determined on the same scale for all players based on their skill levels displayed in practice sessions, warm-ups, friendlies, and, competitions. Focusing on individual attributes will enable a better comparison between players who are from different teams, leagues, and countries, as attribute rankings are determined by consistent observation and independent of the system they are in. In doing so, my model will not fall victim to the aforementioned scenarios that provide erroneous results. Further, my model will be based on fewer parameters than those developed in existing literatures, thereby minimizing multicollinearity in the parameters. My research will also be able to objectively state whether one can value certain intrinsic attributes of a player to the extent where these attributes are equally adequate, if not better, parameters of predicting transfer values than those involving parameters that are dependent on factors other than the individual player.

My research still has the following weaknesses with respect to the determination of player attribute ratings and lack of certain external factors, which are becoming increasingly important, as predictor variables. The heaviest criticism of this model is in the construction of individual player attribute rankings by FIFA, and can be summed up into the following points,

- i. attribute rankings are subjective, in that they include biases we have
- ii. attribute rankings are relative, in that there is no way of stating that player X's sprint speed is a 94 on 100, but given that player X's sprint

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

speed is 94 and we know that player Y is slower, we can assign player Y a sprint speed of 90 on 100

- iii. attribute rankings are also based on real live events such as performance statistics and media mentions, so we are not completely removing the player from the system

Although these are strong concerns with the use of attribute rankings, I believe that these rankings encompass the key figures from the existing models and build on them. My model has more limitations dependent on the data and the manual effort being put into the research,

- i. the dataset is restricted to the English Premier League only and contains only 401 data points from four years, which is a small subset of the actual transfers made globally. This is because lot of transfers are as “free agents”, “loans”, or undeclared, which have to be removed as they are not indicators of true transfer value. Given more time and better access to data sources, this issue can be easily avoided.
- ii. Information on performance statistics could also have been used to identify how FIFA includes that in providing ratings to the players
- iii. there is no distinction between pre-season and mid-season transfers, which intuitively seems to be an important factor in determining value. Again, given more time and better access to data sources, one can easily conduct analysis by separating transfers into two groups of transfers – those made in the pre-season window and those made in the mid-season window.
- iv. no external factors of the system surrounding the player were taken into account, although some of these factors might be significant in determining value and not included in the attribute ranking. This is slightly more complicated due to the inability of quantifying status,

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

although we could look at factors such as increase in merchandise and ticket sales.

- v. market behavior such as media hype and bidding wars are not accounted for in this model. This can be solved by getting data on positive and negative media mentions of players in periods leading up to their transfers. Media hype and bidding wars are both highly correlated to media mentions.

Methodology

This research will achieve its purpose of developing a robust econometric model by identifying key attributes as predictor variables that are significant in determining the transfer value based on the data available from FIFA game ratings. It will also delineate reasons why the overall rating of a player is more significant more than the identified key attributes for that position. Finally, I will consider age as a parameter to assess the trend of age on transfer value.

In order to successfully test the accuracy of the model, I am going to extend the model obtained from data of players that have already been transferred to all the players within the FIFA dataset. A better test of this model's efficacy will be done over time as the players within this FIFA dataset are transferred and their transfer values are compared to those generated by this model after accounting for changes in their attribute data.

I. Data

Transfer value data of players was obtained from transfermarkt.com, which has a compilation of declared soccer transfer values globally. This was restricted to the English Premier League (EPL), because the EPL is the world's most popular soccer league and because I had planned on building a website scraper to get information on media mentions, which would be easiest if the language were English. This data was obtained for the time period 2013 – 2016, as this was a period that witnessed 27 of the 50 most expensive transfers recorded in history, with 8 of the 10 most expensive transfers in EPL history. Transfermarkt also provides transfer values of free agents as a value of 0, while

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

loans and undeclared were left blank. All transfers with missing values or values of 0 were deleted. Further, some players were transferred between clubs within the EPL and so their information was recorded twice. All such cases had duplicates deleted, so as to record the player's transfer value information only once. Transfermrkt also has limited information on club promotions from the club academy to the first team, which are listed as transfers but are minimal compared to transfers made for players from other first teams.

Player attribute data was obtained from sofifa.com, a website that has tracked player attribute rankings of all players in the FIFA video games tracing back to FIFA 2007. FIFA 2017 has an algorithm that oversees 5.4 mn data points comprising 700 clubs and 18,000 players. They have a 9,000-member network made up of data scientists, professional scouts, coaches, and fans. This network is responsible for attending practice sessions, friendlies, and competitive matches to provide a relative ranking of all the 18,000 players that FIFA has on its game. Players are also called into the FIFA studio to test their attributes and set a benchmark. Inherently, factors such as performance statistics also help set relative rankings. Two players with similar goals scored for the same team are very likely to have similar attributes in the attacking category. Factors such as league and country also affect the attributes, to the extent that a player in the English Premier League with similar performance statistics as a player in a lower league will have considerably better attribute rankings. FIFA claims that its attribute ratings start as guesswork for new players, but improve drastically over time as their network witnesses these players. Moreover, player attribute data is consistently updated even after the game is released, information that SoFIFA has captured. Hence, I use player attribute data immediately prior to the transfer, and delete all the other attribute data for that player. In the case of multiple transfers for the same player, all attribute data prior to each transfer is included, and each transfer is considered a different data point. Players that have been transferred and recorded on Transfermrkt but are lacking

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

attribute data in SoFIFA are excluded from the dataset as well. All this boils down to a dataset of 401 data points.

II. Analysis

Data analysis starts with an attempt to identify the two key attributes for each position in order to determine whether players can be valued using only two key attributes for that position as parameters. To do this, I created four position binaries – gkp, def, mid, and att. Transfers involving goalkeepers (GK) will result in the corresponding gkp value = 1; transfers involving center backs (LCB, RCB, CB), and full backs (RB or LB), will result in the corresponding def value = 1; transfers involving defensive midfielders (DM, CDM), central midfielders (LCM, RCM, CM), and attacking midfielders (RM, LM, CAM) will result in the corresponding mid value = 1; transfers involving wingers (LW, RW), forwards (CF, RF, LF, FW), and strikers (SS, ST) will result in the corresponding att value = 1. I then regress the overall rating of players by position category with attributes corresponding to that position category, as can be seen in Appendix 1. The two most significant attributes for each position are identified from the regression coefficients and new columns are generated with attr1 accounting for the primary attribute rating, and attr2 accounting for the secondary attribute rating for each player depending on the position they're in; attr1 = positioning for goalkeepers, marking for defenders, ball control for midfielders, finishing for attackers; attr2 = handling for goalkeepers, interceptions for defenders, short passing for midfielders, and volleys for attackers. To test the fit of these key attributes, I regress the overall rating of players by position with these two attributes to get an R-squared = 46.32%, and statistically significant correlations of 33.27% for attr1 and 13.75% for attr2. The scatterplots of the residuals with the estimates in Appendix 2 indicate the randomness of the error terms with the predicted estimates. This suggests that these attributes provide a good measure of the overall rating of the player.

Having obtained the two most significant attributes for each position, we want to determine whether managers seek players who excel at the two key position

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

attributes or players with higher holistic ratings. A comparison of two regressions of transfer values, once with overall rating and once with the two key attributes, can help answer this. Regressing transfer value with overall rating gives us an R-squared = 20.75% while regressing transfer value with the two key attributes gives us an R-squared=9.75%. Appendix 3 shows the regression tables. Hence, players with higher overall ratings are more valuable than players with higher key attributes ratings. However, earlier regressions showed that players with high overall ratings are likely to have high attribute ratings as shown by the high R-squared of 46.32%. Therefore, although the data suggests that there is more value to players with higher overall ratings, these players on average also have higher attribute ratings, making it difficult to compare the two metrics individually.

Next, we need to determine whether a player's potential is a better variable than the overall rating. Since I know that transfer age will be another parameter in our model, I first check for collinearity between the parameters by regressing overall rating with transfer age and by regressing potential with transfer age. Results show that regressing overall rating with transfer age is statistically significant and gives an R-squared = 25.08%, while regressing potential with transfer age is not as significant and gives an R-squared = 0.84%. The results have been summarized in Appendix 4. Although, potential is less correlated with age, overall rating is not as correlated as expected and hence is safe to use alongside transfer age in our model.

We now need to test the correlation between transfer value and age at transfer. A cursory regression of transfer value with transfer age gives us a statistically significant negative coefficient for transfer age with an R-squared = 1.01%. This is an intuitive result as managers are likely to pay more for players below the prime age so that the players can develop into performing at their maximum capacity during the peak years at this club. Simultaneously, players above their peak years are likely to be transferred at a lower value because they are depreciating assets. I decide to delve deeper into this correlation and set up four binary variables representing different age groups – players

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

being transferred from academy ($\text{age} \leq 20$), players being transferred before their peak years ($20 < \text{age} < 25$), players being transferred at their peak years ($25 \leq \text{age} \leq 28$), and players being transferred post their peak years ($\text{age} > 28$). Regressing transfer value with the transfer age for different age groups separately provides more interesting results, which have been summarized in Appendix 5, although none of the regressions are completely statistically significant because of the low sample size in each regression. The academy age group has a negative correlation of -1.85 between transfer value and age with an $R\text{-squared}=1.02\%$. This result is intuitive as these players are not being purchased to play games immediately, but are instead bought to develop at the club and play in a few years time. Hence, managers are likely to fork out more money for younger players. The age group of players at their pre peak years has a positive correlation of 0.53 between transfer value and age with an $R\text{-squared}=0.19\%$. Ignoring the significance level, this result makes sense because managers want players who show potential to develop but simultaneously are mentally and physically good enough to start games. The group of players at their peak years has a negative correlation of -0.48 between transfer value and age with an $R\text{-squared}=0.24\%$. This relation is negative because these players are performing at their peak years and managers will pay more for players who have three peak years left as compared to players who are in their last peak year. Hence, younger players within this age group have higher transfer values. Lastly, the age group of players post their peak years, quite predictably, has a higher negative correlation of -1.08 between transfer value and age with an $R\text{-squared}=6.8\%$. This is because they are depreciating assets with few years left in their game-life. Older players are likely to retire sooner, while younger players within this group are old to not be heavily sought after by other clubs, thereby enabling this club to extend cheap contracts to the player until the player retires. This gives us a more vivid explanation of the trend of transfer values of players with player ages.

Predicting transfer value estimates using overall ratings and transfer ages of players and plotting the estimate against actual transfer value data illustrates a poor

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

estimate of the data, while a scatter of residuals against transfer value shows a clear trend suggesting that there are more parameters which are being overlooked. This information is summarized in Appendix 6. Hence, we improve the model by accounting for fixed effects of the year the transfer was made by using 2013 as an indicator variable. Regressing transfer values with overall ratings, transfer age and a dummy variable for the transfer year, we get statistically significant coefficients for overall ratings (1.31) and transfer age (– 1.55) with an R-squared=36.06%. Coefficients for 2014, 2015, and 2016 are 1.28, 1.53, and 3.33 respectively with significance levels increasing in transfer year. As shown in Appendix 7a, on predicting estimates using this linear-linear model, we can observe that the model does not accurately fit the data. Moreover, a scatter of the residuals against the estimate illustrates that the relationship might not be a simple linear relationship, and that there might be a factor causing the parabolic shape of the errors. Hence, we try to better fit the data using an ln-ln model by first generating three new variables – $\ln(\text{transfer value})$, $\ln(\text{overall rating})$, and $\ln(\text{transfer age})$. We then regress $\ln(\text{transfer value})$ to $\ln(\text{overall rating})$, $\ln(\text{transfer age})$ and a dummy variable for the transfer year. This gives us statistically significant coefficients for $\ln(\text{overall rating})$ (10.37), $\ln(\text{transfer age})$ (– 3.86), and the indicator variables of 2014 (0.41), 2015 (0.55), and 2016 (0.60). Further, the R-squared=41.85% which is a 5% increase from the previous model. Information on this model is summarized in Appendix 7b. Due to the improvement in the model, I conduct a last regression to test the ln-linear model. I regress $\ln(\text{transfer value})$ with overall ratings, transfer age and the indicator variables for year of transfer. This model gives us the best representation of the data with a higher R-squared=43.85% and statistically significant coefficients for overall rating (0.15), transfer age (– 0.16), 2014 (0.41), 2015 (0.56), and 2016 (0.61). A scatter of the estimate against the actual data shows us the best fit of the data while the scatter of the residuals against the estimate displays a more random, evenly distributed variance of error terms. However, a scatter of the residuals against $\ln(\text{transfer value})$ indicates that there is another parameter that is causing the errors to have a positive

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

correlation with $\ln(\text{transfer value})$. This suggests that external factors that are not adjusted for in the player's attribute and overall ratings are affecting the transfer value. Hence, my estimate provides a true value of the player's attributes while the true market value depends on certain additional external factors.

Another important observation is the increasing coefficient in the dummy variable of transfer years in all three models. This suggests that the transfer value for a player is highest in 2016 and lowest in 2013, after accounting for overall rating and age. This directly supports the claim that there is a growing trend of increased funding to transfer budget and expenditure on purchasing players, which is inflating the transfer value for the same performing asset. This is a crucial finding because investors can utilize this information as an arbitrage opportunity to purchase players in the transfer market only to sell them back in a year at a higher valuation caused because of the rising overall prices.

Due to limited transfer value data, I could not utilize the entire FIFA player attribute dataset obtained from sofifa consisting of 11,063 players. Extending this model to the larger FIFA player attribute dataset, we get interesting results ranging from 0 to a record-breaking 110.61 GBP. The accuracy of the prediction can only be determined when transfers do occur in the future, although the overall ratings and transfer age will have to be updated, while fixed effects of the years post 2016 will have to be found.

Conclusion and Further Research

This paper provides a fairly comprehensive and justified model to determine the market value of a player's intrinsic attributes and age,

$\ln(\text{transfer value}) = \alpha(\text{overall rating}) + \beta(\text{age at transfer}) + \delta(\text{year of transfer}) + u$
 where δ is a dummy variable that allows the $\text{year of transfer} = 1$ if the transfer is made in 2016, and $\text{year of transfer} = 0$ otherwise. The model provides precise results and will be tested for its accuracy with future transfers of these players.

There are some clear limitations in my model, which should be addressed in future research

Developing a statistical model to predict soccer players' transfer values using EA Sports FIFA video game's intrinsic player skill data as a predictor variable

- i. identification of external factor such as media hype, club budget and length of contract that could directly affect the transfer value of a player. This is difficult to get access to and simultaneously difficult to quantify. However, adding this to the aforementioned model would provide one with a more accurate representation of transfer value accounting for these externalities.
- ii. distinction between pre-season and mid-season transfers to account for emergency transfers.
- iii. macroeconomic changes in a particular nation such as hyperinflation that might result in a higher price at a smaller valuation
